## SUMMARY INFORMATION

DETERMINED	UNITS	RESULTS	LIMIT
Particulate Concentration (STP)	mg/m <sup>3</sup>	16.8	50
Mass Emission (STP)	Kg/hr	0.41	-
Stack Temperature	°C	90	
Gas Velocity	ms <sup>-1</sup>	14.40	
Stack Volume Flow Rate (Actual)	m <sup>3</sup> /hr	32975	
Stack Volume Flow Rate (STP)	m <sup>3</sup> /hr	24401	

All results are reported at reference conditions of 273K, 101.3kPa, wet gas.

### 1. INTRODUCTION

On 23 July 2007, particulate emission testing was undertaken by Advance Environmental, on the Parker asphalt plant at Aggregate Industries UK Limited, Express Asphalt, Coventry.

The purpose of the emission testing was to ensure compliance with the requirements of the permit issued by Coventry City Council under The Pollution Prevention and Control (PPC) regime introduced by the PPC Act 1999.

#### 2. BACKGROUND INFORMATION

The Pollution Prevention and Control Act came into force in December 1999, superseding Part 1 of the Environmental Protection Act, 1990. The Act introduced a new regime of integrated pollution prevention and control (IPPC) for those industrial activities regulated by the Environment Agency and Local Authority Pollution Prevention and Control (LAPPC) for those regulated by Local Authorities. Roadstone coating, mineral drying and cooling and other quarry processes were scheduled for LAPPC under Section 3.5 of Part B of the Pollution Prevention and Control (England and Wales Regulations) 2000, and were brought under the revised regime in March 2003.

To continue operations, all sites operating scheduled processes must obtain a permit from their Local Authority and comply with the conditions contain therein. The conditions will include a requirement to monitor emissions to air both periodically and continuously in accordance with relevant clauses of following process guidance note:-

PG3/15a(04) Secretary of State's Guidance – Roadstone Coating Processes

## 3. MONITORING CONTRACTOR

The emissions test was co-ordinated by Mr K Gough, Company Principal, Advance Environmental. Mr Gough has 18 years experience of undertaking particulate emission testing on plant used in the quarrying and allied industries.

### 4. MONITORING PROTOCOL

#### 4.1 Test method and references

Isokinetic sampling of the contained emission sources was undertaken using the APEX Instruments Inc Method Five isokinetic sampling apparatus in accordance with the main procedural requirements of given within the following British Standards and Technical Guidance Notes:-

- BS ISO 9096:2003 Stationary source emissions. Manual determination of mass concentration of particulate matter.
- Environment Agency Technical Guidance Document (Monitoring) M1 Sampling requirements for monitoring stack emissions to air from industrial installations; and
- Environment Agency Technical Guidance Document (Monitoring) M2 Monitoring of Stack Emissions to Air.

#### 4.2 Sampling Procedure

The work carried out was, as far as was reasonably practical, in accordance with BS ISO 9096.

Isokinetic flow means that sample gases laden with particulates are drawn off at the same velocity as the free stream velocity in the flue. Isokinetic sampling thus avoids possible inertial effects of particulates approaching the vicinity of the inlet nozzle which may result in significant error.

The Apex Instruments test equipment used, is designed to meet the sampling requirements of US EPA Method 5 and with a modified nozzle design, meets the sampling requirements of BS ISO 9096.

The principle of BS ISO 9096 is to draw a known volume of dust laden gas isokinetically through a filter. The weight gain on the filter, after sampling, divided by the gas sample volume equates to the particulate concentration, which in turn can be used to calculate a mass emission.

### 4.3 Sampling equipment

The test equipment is inspected prior to use and the calibration status observed. This includes:-

- *Pitot Tube* All pitot tubes are checked for damage, alignment and that there are no blockages;
- *Manometer* Oil levels, connectors and orientation level are checked;
- Thermocouple Temperature is measured using k type thermocouples. Each thermocouple is inspected for calibration and damage. Digital temperature meters are used in conjunction with k type thermocouples which are also checked for calibration dates;
- *Gas meter* The calibration of the gas meter is checked before and after sampling using a critical orifice.
- Nozzles All nozzles used have been constructed in accordance with BS ISO 9096. Each nozzle is checked for damaged and measured using a vernier caliper on at least 3 planes. Non conforming nozzles will be rejected.
- Balance A Mettler Toledo balance is used to weigh filters. It is calibrated yearly by the manufacturer and checked daily by in-house weights.
- *Filters* Pall quartz membrane filters with a collection efficieny of >99.5% at 0.3microns.

#### 4.4 **Preparation for sampling**

#### 4.4.1 Filter Preparation

Filters are pre-conditioned before arrival on site. The filters are dried in an oven at  $180 \,^{\circ}$ C for a period of at least one hour and then placed to cool in a dessicator for at least four hours. The filters are then weighed on a five figure balance and placed in individual transport containers. Spare filters are prepared to obtain blank values.

#### 4.4.2 Sampling Location

No site visit was undertaken prior to undertaking the sampling procedure, as monitoring had previously been undertaken at the site, during which time the sampling position, working platform, sampling ports, access and safety precautions were found to be satisfactory.

The internal dimension of the flue was known from the previous monitoring undertaken. However, further measurements were taken to check that the internal diameter had not changed.

Prior to sampling a pressure and temperature survey, using a pitot static tube, a micromanometer, a digital thermometer and a nickel-chromium/nickel-aluminium thermocouple, is carried out to check whether the flow conditions meet with the requirements of BS ISO 9096. From this initial survey sample locations, isokinetic flow rates, nozzle size, and sample period can be calculated. Sampling

#### 4.5 Sample collection

A leak check is carried out before and after sampling to confirm all the suction is drawn through the nozzle.

With the required isokinetic flow rates known the sample probe was inserted into the stack at  $90^{\circ}$  to the gas flow, this is to stop any particulate matter impinging on the filter before sampling.

The filter head and probe were allowed to obtain the stack gas temperature.

The initial gas meter volume was noted and the suction device and timer started. The correct flow rate for isokinetic sampling was set and the nozzle positioned to face parallel to the gas flow.

Sampling was then carried out for the planned duration and number of sample points, recording all the necessary data for final calculations. On completion, the suction device, timer were stopped and the final gas meter volume recorded.

The probe was removed from the process stack and a further leak test carried out prior to removal of the filter, which was subsequently removed and placed in a storage container.

Any residual particulates upstream of the filter was washed with water and acetone into an appropriate beaker.

The above procedures were then repeated to obtain duplicate samples.

At all times during the sampling procedure the sampling technicians were in contact with the process operator to ensure that the plant was in full production and there were no changes in the process that might affect the representative nature of the samples collected.

#### 4.6 Analysis of samples

On returning to the laboratory, the used filters were dried in an oven at 160 °C for a minimum of one hour and then desiccated and weighed as before. The water/acetone washings are first evaporated, without boiling, then dried and weighed as above. The total particulate mass is the sum of the differential filter weight added to the differential water/acetone component.

#### 4.7 Calculation of results

The calculations were made using the formula specified in BS ISO 9096.

The recorded filter weights, velocity, temperature, sampling duration and internal flue dimensions were than used to calculate:-

- the mass rate of solids emission in kg/hr; and
- the solids concentration in  $mg/m^3$ .

#### 4.8 Sampling Results

Two particulate tests were carried out, under continuous operating conditions, to assess the emission concentration in the exhaust gases. The sample time of each test was 32 minutes, primarily due to the limited production time to enable completion of the test.

At the time of sampling, a mean particulate matter concentration of 16.8  $mg/m^3$  at reference conditions. It can be concluded, therefore, that the emission from this plant was found to comply with the emission limit currently imposed.

#### 4.9 Comments

On the completion of sampling, the data from the PCME DT 990 continuous emission monitor was interrogated and the average results, which were recorded during each measurement period, noted. Levels of 15.0307 mg/m<sup>-3</sup> (Test 1) and 13.3336 mg/m<sup>-3</sup> (Test 2) were obtained together with an existing calibration factor of 6.9221. It can be concluded that the monitor could be adjusted to improve the level of accuracy and requires an adjustment of the calibration factor to 8.1880.

Full test data demonstrating procedural compliance with BS ISO 9096 for total particulate monitoring is provided the following sections.

## 5. SAMPLING RECORDS

# 5.9 - Main conditions for compliance with BS ISO 9096:2003

The following requirements must be met:

#### **Preliminary Velocity Survey**

	Pass	Fail
No negative flow at sampling points	*	
Direction of gas flow within 15° of flue axis	*	
Pitot-static pressure differential greater than 5 Pa ( 3m/s )	*	
Ratio of highest to lowest pitot-static readings less than 9:1	*	

#### Sampling procedure

Sampling plane was corectly positioned	*	
Sampling centroids of equal area	*	
bumping contoins of equal area	I	
Nozzle was facing upstream to within $\pm 10^{\circ}$	*	
Leak check performed	*	
Constant 'at' during cumulative sampling	*	

#### **Post Sampling Operations**

Leak test performed	*	
Isokinetic rate 95 % to 115 %	*	
Samples achieved stable weights	*	

Note : A single tick in the "fail" column indicates that this test does not comply with the full provisions of BS ISO 9096:2003. Due to site/sampling locations it is not always practically possible for all the conditions to be met. Best practical means are employed to try and achieve a representative result.
